Actuarial Geometry

Stephen Mildenhall Aon Re Services, Chicago IL

April 11, 2008

Outline

- 1. Framework
- 2. Losses are not homogeneous with respect to volume
- 3. Insurance risk is not volumetrically diversifying
- 4. Homogeneous model is not even "locally" appropriate
- 5. Empirical data and supporting evidence
- 6. Four models based on Levy processes
- 7. Why bother with general Levy processes vs. compound Poisson processes?
- 8. So what? Can we see impact in prices?

1. Framework

	Risk Theory	Finance	Actuarial
1900s	Bachelier		Bureau rates
1000	Lundberg		Bureau rates
1930s	Levy, Kolmogorov,		Bureau rates
1950s	Khintchine		
		Portfolio theory	Bureau rates
1960s		CAPM	Investment income
1970s	Buhlmann Borch	Systemic vs. diversifiable risk	Ferrari, ROE
		Option pricing	1978 u/w profit
1980s		Fair rate of return	
1990s	Artzner et al. Coherent Measure of Risk	Phillips, Cummins	Cat Models
2000s	Convex risk measures	Froot et al.	2004 u/w profit
		Merton-Perold Zanjani Boyer	Idiosyncratic risk matters

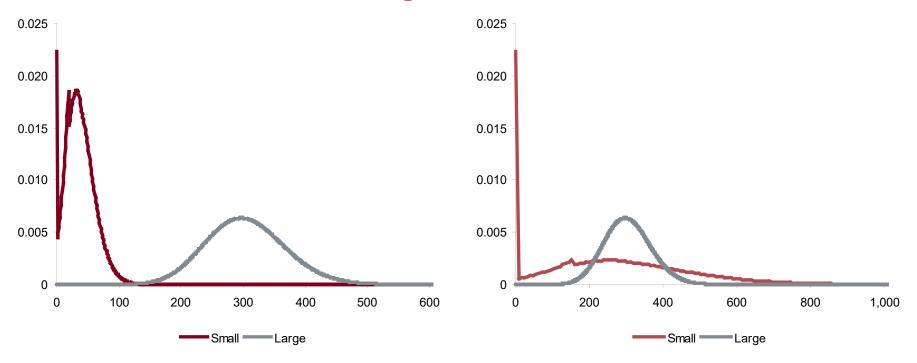

2. Losses are not Homogeneous wrt Volume

- Expected Loss (\$) = Volume (\$ / t) x Time (t)
 - For fixed t (t=1), expected loss = volume
- ► A(x,t) := aggregate losses from volume x insured for time t
 - E[A(x,t)] = xt = expected loss
- **Homogeneous** model: $A(x,t) = xR_t$
 - R_t a "return" variable
 - For assets: x is position size and R_t is return or unit price
- Homogeneity implies
 - Shape of aggregate loss distribution independent of volume
 - No volume based diversification
 - A(x,t) has constant coefficient of variation (volatility) with x
 - Recall coefficient of variation = CV = standard deviation / mean
- Homogeneous models are not appropriate for insurance
 - Consider probability of zero losses: Pr(xX=0)=Pr(X=0) independent of volume x

2. Losses are not Homogeneous wrt Volume

- Consider probability of zero claims in small and large books
- Compound Poisson aggregate losses
 - Small: claim count 4
 - Large: claim count 32
- ▶ Left plot unscaled; right plot scaled
- ▶ Homogeneous distributions would be indistinguishable in scaled plot
 - Note decrease in variance on right hand plot

2. Losses are not Homogeneous wrt Volume

- ▶ Geometric Brownian motion model is homogeneous wrt volume
 - $S_t = S_0 \exp((\mu \sigma^2/2) t + \sigma B_t)$, where B_t is a Brownian motion
 - Volume = S_0
 - Return = exp($(\mu \sigma^2/2) t + \sigma B_t$)

3. Insurance Risk is not Volumetrically Diversifying

- Meaning
 - CV(A(x,t)) does not tend to zero as x increases, for fixed t
- Practical meaning
 - It is impossible to diversify away all insurance risk by growing larger
- ▶ How to investigate?
 - CV(A) = CV(A/p) = CV(loss ratio), p = fixed premium
 - Look at volatility in loss ratio with volume
- Data source: NAIC Annual Statement, Schedule P
 - Gross, ultimate loss ratios
 - 10 accident year history
 - Major lines: WC, Commercial Auto, HO, PPA, CMP, Other Liability etc.

SCHEDULE P - PART 1D - WORKERS' COMPENSATION

3. Risk is not Volumetrically Diversifying

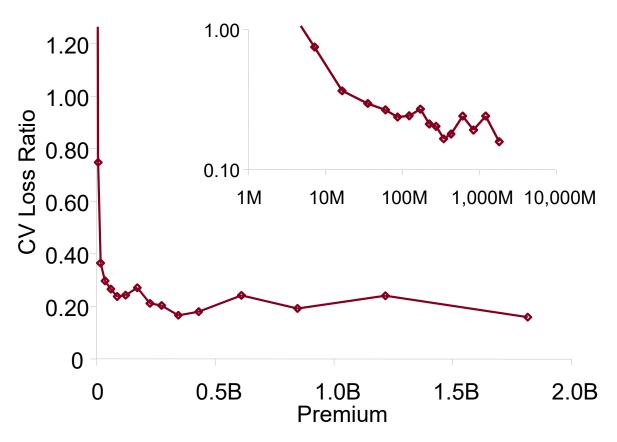

2004 CV Gross Loss Ratio vs. Premium Commerical Multiperil

3. Risk is not Volumetrically Diversifying

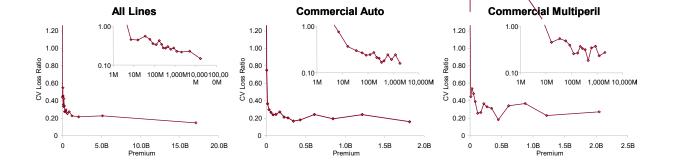

Commercial Auto

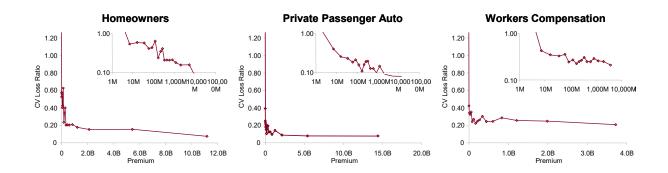

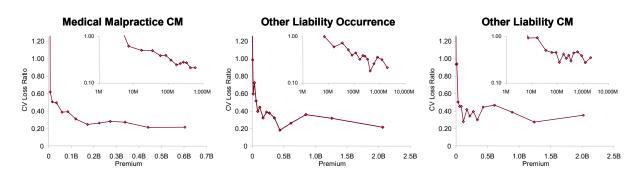

Risk not constant – not homogeneous

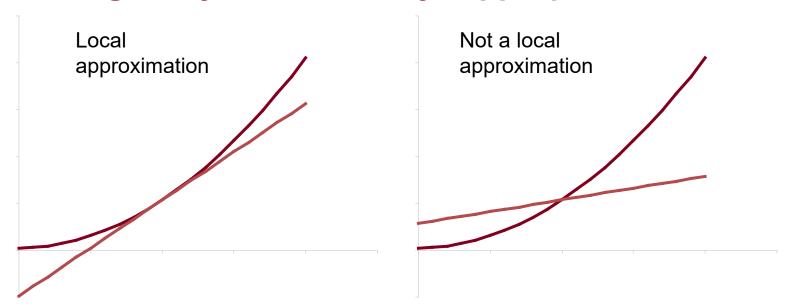

Risk decreases to asymptote

- ▶ Local approximation: one holding to first order in a neighborhood of a point
 - First-order equality required by any theory considering derivatives (Myers-Read)
 - Equality ≠ first order approximation
- Requires notion of derivative which requires a direction

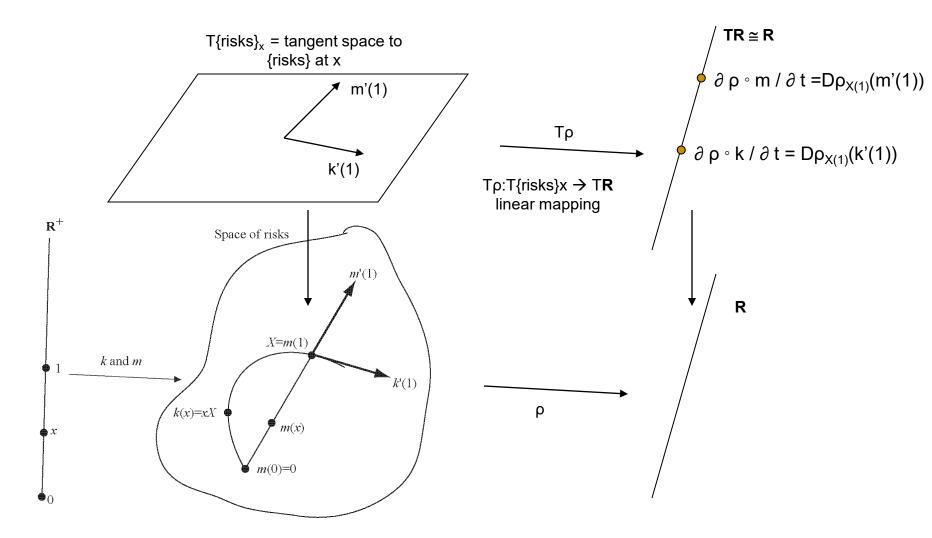

- ▶ For simplicity, ignore volume x, and assume x=1
- Model X(t) as a (mixed) compound Poisson distribution = family aggregate losses and suppose
 - Expected claim count = t
 - E(severity) = 1
 - So E(X(t)) = E(severity) x E(claim count) = t
- ▶ A homogeneous approximation to the family X(t) near t=1 is given by t X(1)
 - Will show this is **not** a local approximation
- ▶ Have two maps from $[0,\infty)$ → { risks }, agreeing at t=1:
 - m(t) = X(t), Meyers embedding
 - k(t) = t X(1), asset or Kalkbrener embedding

- ▶ Let ρ : { risks } \rightarrow **R** be a real-valued risk measure
 - Standard deviation, downside risk, higher moment, percentile (=Value-at-Risk, VaR), TVaR
 - Tasche, Denault, Fischer, Myers-Read,... show we should be interested in $\partial \rho / \partial t$, the rate of change of ρ with volume in the line
- ▶ Two compositions $\rho \circ k$, $\rho \circ m$: $[0,\infty) \rightarrow \mathbf{R}$ both give single valued functions of a single real variable
- Meyers, RTS 2005, showed for ρ = standard deviation
 - $\partial (\rho \circ k) / \partial t \neq \partial (\rho \circ m) / \partial t$
- In terms of derivatives of ρ (picture):
 - $\partial \rho \circ k / \partial t = D\rho_{X(1)}(k'(1))$ and $\partial \rho \circ m / \partial t = D\rho_{X(1)}(m'(1))$
 - Implies directions m'(1) ≠ k'(1)
- ▶ What are the directions m'(1) and k'(1)?

Why is m drawn as the straight line?

Table 1: Possible characterizations of a ray in \mathbb{R}^n

Characterization of ray	Required structure on \mathbb{R}^n
α is the shortest distance between	Notion of distance in \mathbb{R}^n , differen-
$\alpha(0)$ and $\alpha(1)$	tiable manifold
$\alpha''(t) = 0$, constant velocity, no acceleration	Very complicated on a general manifold.
$\alpha(t) = t\mathbf{x}, \mathbf{x} \in \mathbb{R}^n.$	Vector space structure
$\alpha(s+t) = \alpha(s) + \alpha(t)$	Can add in domain and range, semigroup structure only.

- ▶ What is the addition operator "+" in { risks }?
 - Assets: vector space structure with basis of return variables (3X ok)
 - Insurance: convolution of random variables (3X not ok, X₁+ X₂ + X₃)

- Defining property for straight-line in { risks }
 - m(s + t) = m(s) * m(t), convolution sum of random variables
- ▶ Levy process satisfies m(s + t) = m(s) * m(t)
 - Additive, independent, homogeneous increments, stochastically continuous
- Examples of Levy processes
 - Brownian motion, compound Poisson, drift, combinations
- What are k'(1) and m'(1)?
 - m_t defines a family of probability measures
 - Properties manifest through **operator action** on functions $< f, m_t > = \int f(x) dm_t(x)$
 - Derivative should be a family of linear functionals f → m'(f)(t) indexed by t
 - Fundamental Theorem of Calculus: <f,m(1)> <f,m(0)> = ∫ m'(f)(t) dt
 - Differentially: $m'(f)(0) = \lim_{t\to 0+} [E(f(X_t) f(X_0))] / t$, where X_t has distribution m(t)

- ▶ $\lim_{t\to 0}$ [E(f(X_t) f(X₀))] / t defines infinitesimal generator of Markov process
- ▶ For compound Poisson m, let J be distribution of jump sizes, E(J)=1
- For small t, Pr(jump) = λt, so, conditioning on presence of a jump

•
$$E(f(X_t)) = \lambda t E(f(J)) + (1 - \lambda t) f(0)$$

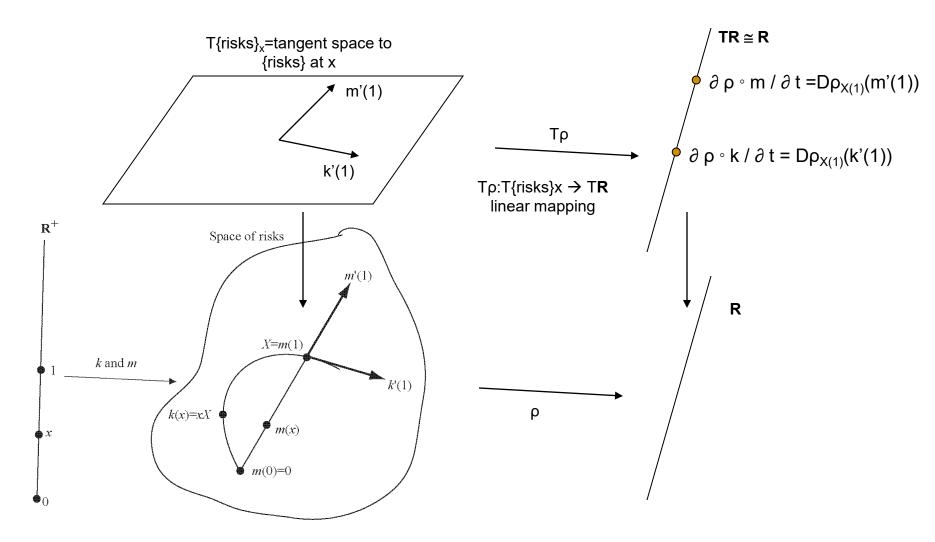

and hence

- $m'(f)(0) = \lambda (E(f(J)) f(0))$
- ▶ For k, $E(f(X_t)) = E(f(tX)) = f(0) + tE(X) f'(0) + O(t^2)$, so
 - k'(f)(0) = E(X) f'(0), which is completely different

Example

J=1, constant, X=Poisson(λ). m'(f)(0) = λ (f(1)) - f(0)) k'(f)(0) = E(X) f'(0) = λ f'(1)

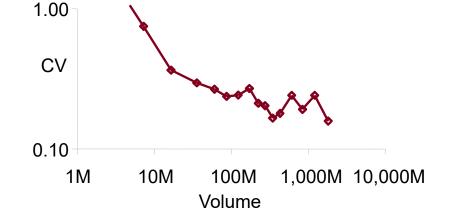

5. Empirical Evidence

- Data supports two hypotheses
 - Risk is not homogeneous: CV not constant wrt volume
 - Risk is not volumetrically diversifying:
 CV has asymptote

- ▶ Can we say more?
- Levy process based models
 - A(x,t) = X(xt)
 - A(x,t) = X(xZ(t)), Z a positive, increasing Levy process (a subordinator)
 - A(x,t) = X(xCt), E(C)=1, C is called a mixing variable
 - A(x,t) = X(xCZ(t))

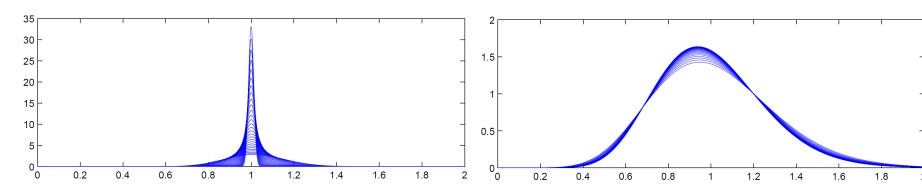

Mixing Variables & the Distribution of Normalized Loss Ratios

- Mixed compound Poisson: A = X₁+...+XN, N|C ~ Poisson(nC), E(C)=1
- Normalized Loss Ratio NLR = A / E(A)
- Dichotomous behavior of normalized loss ratios

No parameter uncertainty: leads to unrealistic aggregate loss distribution as expected losses increase

Including parameter preserves actual variability observed in data for large insurers

If C is constant, NLR converges to 1.0 in distribution

Illustration shows aggregates with Poisson frequency & larger & larger values of E(A)

If C is not constant, NLR converges to C in distribution

Illustration shows aggregates with negative binomial frequency (gamma mixing) & larger & larger values of E(A)

Key Technical Result

- ▶ If severity X has a variance then A / E(A) converges in distribution to C
- Proof:

Let M_D be the moment generating function of D, for D=A, C, N or X. Let x=E(X), n=E(N), a=E(A)=nx. Then

$$\lim_{n\to\infty} M_{A/a}(t) = \lim_{n\to\infty} M_A(t/a)$$

$$= \lim_{n\to\infty} M_C(n(M_X(t/a) - 1))$$

$$= \lim_{n\to\infty} M_G(n(M_X'(0)t/nX + R(t/nX)))$$

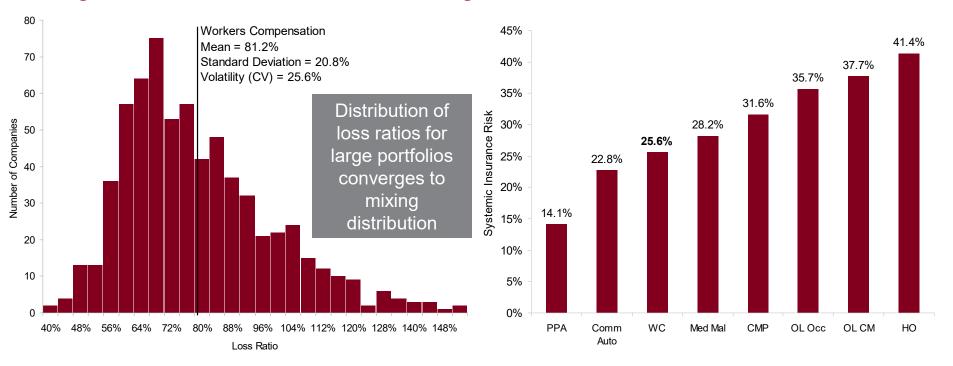

$$= \lim_{n\to\infty} M_C(t + nR(t/nX))$$

$$= M_C(t)$$

For some remainder function $R(t)=O(t^2)$. The assumptions on X guarantee that $M_X'(0)=x=E(X)$ & that the reminder term in Taylor's expansion is $O(t^2)$. The result follows because a distribution is uniquely determined by its moment generating function.

Systemic Insurance Risk by Line

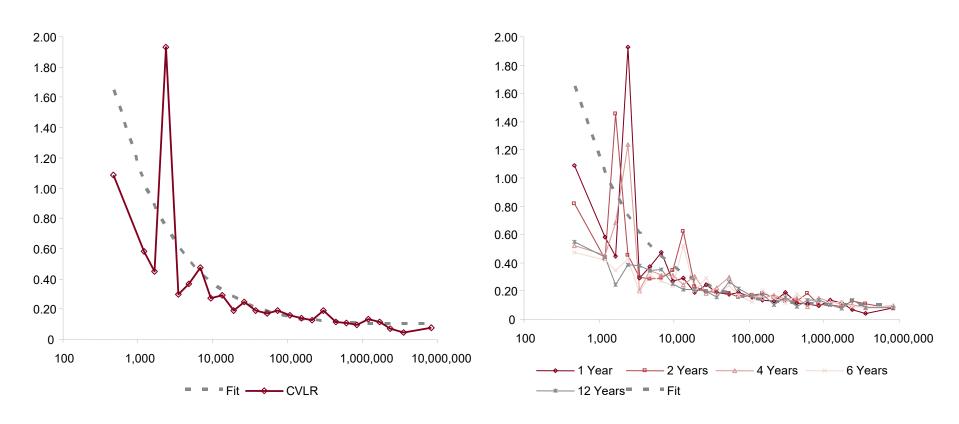

- Systemic risk quantified using study of Schedule P gross ultimate loss ratios, cf. Slide 9
- Systemic insurance risk includes line of business uncertainty caused by

Pricing cycle
Frequency & severity trend
Economic activity

Loss reserve uncertainty Legal & judicial changes Weather

Volumetric/Temporal Symmetry

- ▶ Consider volatility of A(x,t), A(2x,t/2), A(4x,t/4) etc.
- Same relationship between volatility and volume, xt
- Consistent with volumetric/temporal symmetry

6. Four Levy Process Models

$$A(x,t) = X(xt)$$

$$A(x,t) = X(xZ(t))$$

$$A(x,t) = X(xCt)$$

$$A(x,t) = X(xCZ(t))$$

$$A(x,t) = xR(t)$$

Table 2: Variance of IM1-4 and AM

			Divers	sifying
Model	Variance	v(x,t)	$x \to \infty$	$t \to \infty$
X(xt)	$\sigma^2 x t$	$\frac{\sigma}{\sqrt{xt}}$	Yes	Yes
X(xZ(t))	$xt(\sigma^2 + x\tau^2)$	$\sqrt{rac{\sigma^2}{xt}+rac{ au^2}{t}}$	No	Yes
X(xCt)	$xt(\sigma^2+cxt)$	$\sqrt{\frac{\sigma^2}{xt} + c}$	No	No
X(xCZ(t))	$x^{2}t^{2}\left(\frac{(c+1)\tau^{2}}{t}+c\right) + \sigma^{2}xt$	$\sqrt{\frac{\sigma^2}{xt} + \frac{\tau'^2}{t} + c}$	No	No
xX(t)	$x^2\sigma^2t$	σ/\sqrt{t}	Const.	Yes
$\tau' = (1 + c)\tau$				

6. Four Levy Process Models

Which model is consistent with the data?

•
$$A(x,t) = X(xt)$$

no

Volumetrically diversifying

•
$$A(x,t) = X(xZ(t))$$

no

Volumetric/temporal asymmetry

•
$$A(x,t) = X(xCt)$$

Yes

•
$$A(x,t) = X(xCZ(t))$$

no

Volumetric/temporal asymmetry

•
$$A(x,t) = xR(t)$$

no

Constant volatility with volume

Directions and Credibility

- Levy process defines direction through jump distribution (modulo drift, Brownian component)
 - Frequency mixing, C or Z, corresponds to speed along a defined direction
 - Severity mixing corresponds to different direction

7. Why bother with Levy Processes?

- Paper uses compound Poisson distributions as examples for simplicity
- Why bother with general Levy processes?
 - Publishing cottage industry!
- ▶ "Infinite activity" Levy processes include processes with X(1) distributed as
 - Lognormal
 - Pareto
 - Gamma
 - Laplace
 - Weibull (α <1; α >1 is not infinitely divisible)

8. So What? Can we see the impact in prices?

- ▶ Idiosyncratic risk matters, price should decrease with size
 - Price = margin or spread over actuarial rate
 - Size = expected loss = xt; t=1
 - Large depends on particulars of severity distribution
- Umbrella and high limit policies
 - Companies target higher price for higher process risk
- Reinsurer notion of "balance"
 - Unbalanced cover has premium < limit
- ▶ Large accounts, package policies
 - Probably top-line focus rather than risk theory
- Myers-Cohn
